References vs Pointers

SEND FEEDBACK

## References vs Pointers

Pointers and references can have similar use cases in C++. As seen previously both references and pointers can be used in pass-by-reference to a function. Additionally, they both provide an alternative way to access an existing variable: pointers through the variable's address, and references through another name for that variable. But what are the differences between the two, and when should each be used? The following list summarizes some of the differences between pointers and references, as well as when each should be used:

References Pointers Pointers can be declared without being initialized, which is References must be initialized dangerous. If this happens mistakenly, the pointer could be when they are declared. This means that a reference will pointing to an arbitrary address in memory, and the data associated with that address could be meaningless, leading to always point to data that was undefined behavior and difficult-to-resolve bugs. intentionally assigned to it. Pointers can be null. In fact, if a pointer is not initialized References can not be null. immediately, it is often best practice to initialize to nullptr, a This means that a reference should point to meaningful special type which indicates that the pointer is null. data in the program. When used in a function for pass-by-reference, a pointer must When used in a function for be dereferenced in order to access the underlying object. pass-by-reference, the reference can be used just as a variable of the same type would be.

References are generally easier and safer than pointers. As a decent rule of thumb, references should be used in place of pointers when possible.

However, there are times when it is not possible to use references. One example is object initialization. You might like one object to store a reference to another object. However, if the other object is not yet available when the first object is created, then the first object will need to use a pointer, not a reference, since a reference cannot be null. The reference could only be initialized once the other object is created.
